

Review of: "Evaluation of Chemical Content and Phytochemical Composition of Yemeni Almond Cultivars"

Aylin Celile Oluk

Potential competing interests: No potential competing interests to declare.

A study was conducted to investigate the nutritional properties of almond trees grown in Yemen.

The most fundamental problem with this study is that the features investigated were revealed as a result of a single-year study. These studies can be meaningful with the same cultivars either in different locations or with two-year data.

Units in tables and text should be the same. Please change to mg 100 g¹ instead of mg/100 grams.

I recommend rewriting the 'Phytochemical compounds content' section. Attention should be paid to units. It was not clear which was the control sample. It should be explained why the 'yield' parameter in Table 5 is given.

The statistical method used for clustering and correlation analyses should be given.

Literature in the text and in the reference list should be checked, and citations should be made correctly.
