The study titled "Effects of Cinnamon on Cancer Prevention and Progression" deals with an important subject. Drug discovery, especially that derived from natural origins, is an important trend, especially against chronic and serious diseases. Inexpensive costs and mild adverse/side effects are the main benefits of natural compounds impacting this trend. The current study is a short review discussing the effects of some of cinnamon's components against cancer and their modes of action. Minor revisions are essentially needed, including the following items that seem useful for external readers.

The antiproliferative activity revealed by each compound explored should be mentioned (quantitatively) relative to the standard reference (for example, those on page 3, third paragraph, lines 9-11; fourth paragraph, lines 1-3). The same words are for the modes/mechanisms of action mentioned throughout the entire article.
