The study presents important data to enable the implementation of general preventive measures in the university, involving students, professors, and workers. It is a good exercise to improve the health of the university population through awareness campaigns throughout the community. The study is a good start to continue with permanent monitoring that allows a better approximation of atmospheric pollution, its temporality, and its effects on the health of the university population, in addition to being able to identify the main sources of atmospheric and climatic pollutant variables. However, it is necessary to improve the methodology, specifically the design of the study; the ideal would be a cohort study that considers a period that allows measuring seasonal variability and the effect on health through a questionnaire or biomarkers, for example, interleukins or spirometry for pulmonary function.
